Form Approved
OMB No. 0704-0188

The public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing the burden, to the Department of Defense, Executive Service Directorate (0704-0188). Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ORGANIZATION.

1 **1.0 Introduction**

2
3 In 2004, the partnering team engaged in resolving environmental matters at the Ravenna Army
4 Ammunition Plant (RVAAP) in Ohio developed a Facility-Wide Groundwater Monitoring
5 Program (FWGWMP). One of the accomplishments of FWGWMP was the establishment of
6 groundwater background concentrations for a specific list of inorganic elements. This initial
7 effort was based on a limited sample set. Since that time, the FWGWMP has continued to
8 collect groundwater data from 36 wells on a quarterly basis and five wells on a semi-annual
9 basis. With a more robust database now available, the background concentrations were updated
10 using the Ohio Environmental Protection Agency (OEPA) approved protocols and also with
11 statistical techniques based on utilizing the entire site-wide data.

12
13 This memo outlines the procedures and results of background analyses of metals in groundwater
14 samples from the RVAAP Site in Ohio. The findings presented are offered for discussion and
15 perspective for future decision-making.
16

17 **2.0 Site Description**

18
19 Past Department of Defense (DOD) activities at the RVAAP date to 1940 and include the
20 manufacturing, loading, and storage of military explosives and ammunition. Until 1999, the
21 RVAAP was identified as a 21,419-acre installation. The property boundary was resurveyed by
22 the Ohio Army National Guard (OHARNG) over a two year period from 2002 and 2003 and the
23 actual total acreage of the property was found to be 21,683.289 acres. As of February 2006, a
24 total of 20,403 acres of the former 21,683 acre RVAAP have been transferred to the United
25 States Property and Fiscal Officer (USP&FO) for Ohio for use by the OHARNG as a military
26 training site.
27

28 The current RVAAP consists of 1,280 acres in several distinct parcels scattered throughout the
29 confines of the OHARNG Ravenna Training and Logistics Site (RTLS). The RVAAP and the
30 RTLS are collocated on contiguous parcels of property and the RTLS perimeter fence
31 completely encloses the remaining parcels of the RVAAP. The RTLS is in northeastern Ohio
32 within Portage and Trumbull Counties, approximately 4.8 kilometers (3 miles) east-northeast of
33 the city of Ravenna and approximately 1.6 kilometers (1 mile) northwest of the city of Newton
34 Falls (Figure 1). The RVAAP portions of the property are solely located within Portage County.
35 The RTLS (inclusive of the RVAAP) is a parcel of property approximately 17.7 kilometers (11
36 miles) long and 5.6 kilometers (3.5 miles) wide bounded by State Route 5, the Michael J. Kirwan
37 Reservoir, and the CSX System Railroad on the south; Garret, McCormick, and Berry roads on
38 the west; the Norfolk Southern Railroad on the north; and State Route 534 on the east (see
39 Figures 1 and 2). The RTLS is surrounded by several communities: Windham on the north;
40 Garrettsville 9.6 kilometers (6 miles) to the northwest; Newton Falls 1.6 kilometers (1 mile) to
41 the southeast; Charlestown to the southwest; and Wayland 4.8 kilometers (3 miles) to the south.
42 When the RVAAP was operational the RTLS did not exist and the entire 21,683-acre parcel was
43 a government-owned, contractor-operated (GOCO) industrial facility. The RVAAP Installation
44 Restoration Program (IRP) encompasses investigation and cleanup of past activities over the
45 entire 21,683 acres of the former RVAAP. Therefore references to the RVAAP in this document

- 1 are considered to be inclusive of the historical extent of the RVAAP, which is inclusive of the
- 2 combined acreages of the current RTLS and RVAAP, unless otherwise specifically stated.

3.0 Technical Approach

Background groundwater concentrations were calculated using two different methods:

1. The quartile method as outlined by the Ohio EPA, and,
2. The 95% Upper Tolerance Limit (95UTL) of groundwater concentrations.

Background calculations were based only on background well samples collected between the second quarter of 2005 and the third quarter 2007. The background exceedances analyses utilized all wells sampled within that same time period.

In performing the analysis, “non-detects” were assigned a value of zero. The general practice in statistical analysis of environmental data is to replace non-detect values by 1/2 the reported lab detection limit RDL or some other appropriate surrogate. However, the substitution of surrogates is dependent on the % of non-detects in the sample. For datasets containing a small percentage of non-detects, defined as 15%, substitution by a suitable surrogate value does not create unnecessary bias in the dataset. As the percentage of non-detects increases, bias is introduced that will alter the distribution of the dataset and any results of statistical analysis based on this biased data. This is particularly true for datasets that contain more than 50% non-detects and the surrogate value (normally 1/2 RDL) is much greater than the actual detections. In the Ravenna database for all analytes, with the exception of Arsenic, the value of 1/2 RDL is greater than between 51% to 100% of the actual measured detections (see Table 3.1). Therefore, a substitution of any surrogate value will result in a distribution that is biased high.

Both methods utilized in the analysis rely on the upper portion of the data set. Thus, using a data set biased high by substitutions will result in background statistics skewed to higher values that are not representative of measured values or true background concentrations. This is reflected in Table 3.2, that compares the average concentrations for each analyte based on using ND=0 and ND = 1/2 RDL. The table clearly shows that by substituting ND = 1/2 RDL the average concentrations have in some case increased by orders of magnitude. Thus, because of these reasons [(1) the high percentage of non-detects; (2) 1/2 RDL values much greater than actual detection; and, (3) the importance of the upper portion of the distribution] it is justified to utilize ND =0 in the analysis.

The quartile method is a non-parametric method and as such it makes no assumption about the distribution of the data set. The 95% UTL method as defined assumes that the data follow a normal distribution. If the data follows a lognormal distribution the formula is applied to the log transformed data. In the case where data do not follow normal or lognormal distribution, the 95% UTL is defined as the maximum value in the dataset.

Data were segregated by aquifers, i.e. the unconsolidated and bedrock aquifers. Separate analyses were performed for filtered and unfiltered samples. In addition, the UTL approach was applied to data from background wells sorted by their respective geologic formation. Groundwater locations were grouped for analysis as shown in Tables 3-3 and 3-4. Brief descriptions of the statistical techniques are provided below.

1 Table 3-1: Percentage of Data Less than 1/2 RDL

Analyte	1/2 RDL > Detected Concentration	% Non Detect

5

1 **3.1 The Quartile Method**

2
3 The background concentration based on the quartile method is calculated as the upper limit of
4 the interquartile range of the existing data using the formula:

5
6 Background Concentration = $Q_3+k(Q_3-Q_1)$

7
8 Where

9
10 Q_1 = the lower quartile represented by the 25th percentile of the dataset

11 Q_3 = the upper quartile represented by the 75th percentile of the dataset

12 $Q_3 - Q_1$ = the interquartile range representing the range of the middle 50% of the dataset and k is
13 a constant. A k value of 1.5 is generally recommended for background calculations and was used
14 in this analysis

15
16 For further information on the method the reader is referred to Ohio EPA, 2004 and Helsel, D.R.
17 and R.M. and Hirsch, 1995.

20 **3.2 The 95% Upper Tolerance Limit (95UTL)**

21
22 The 95UTL is the upper limit of the tolerance range within which a specified proportion of the
23 dataset (i.e. the coverage) will be below, at the 95% confidence level. For determination of
24 background concentrations, coverage of 95% is normally recommended and used in this analysis.

25
26 The background concentrations based on the 95UTL value are calculated using the following
27 formula:

28
29 Background Concentration = $\bar{X} + k\sigma$

30
31 Where

32 \bar{X} = the mean concentration of the dataset under investigation

33 σ = the standard deviation of the dataset under investigation and

34 k = the tolerance factor which is dependent on the sample size and coverage required for the
35 analysis.

36
37 For further information on the method the reader is referred to USEPA, 1989.

39 **3.3 Evaluation of Compounds in Background Well Samples**

40 During the sampling period between 2005 and 2007, the detected concentrations of constituents
41 of potential concerns (COPCs) have in some cases exceeded established background values.

42 Fundamentally, false positives would be expected to occur with the 95UTL approach. However,

1 it is difficult to distinguish false positives versus exceedances on a point-by-point basis. When
2 using 95UTL, the likelihood of false positives for each individual comparison (each analyte in
3 each sample) is 5% and the error increases rapidly as the number of analytes and/or sample
4 numbers increase. For example, if there are 10 analytes, after one year of quarterly sampling, the
5 false positive rate is 87%, i.e. there is an 87% chance that at least one of the individual
6 comparisons caused a false positive. Such an error rate is by far in excess of the acceptable
7 range.

8
9 NewFields conducted an additional review using an approach that avoids the point-by-point
10 comparison. This work was developed and described in reports from the US Navy (NFESC,
11 2004) and the US Geological Survey (USGS, 2006). These works were completed due to similar
12 observations from other data using the 95UTL approach. In simple terms, the approach uses all
13 data, both background and non-background, to determine if the two groups are the same or
14 different, thereby mitigating the impact of isolated exceedances. The following sections describe
15 the approaches used.

16 **3.3.1 Inorganic Detections in Background Well Samples**

17 Wells were characterized as background or non-background as provided in Table 3-5. Statistical
18 comparisons of contaminant distributions in groundwater from background and non-background
19 wells at the site were performed using the t-test and the Mann-Whitney test. The t-test is a
20 parametric test used to test the null hypothesis that data in two samples are taken from the same
21 population against the alternative hypothesis that they are from different populations. The t-test
22 assumes that the two samples are approximately normally distributed. The test works by
23 comparing the means of the samples and determining whether they are significantly different. In
24 this analysis a significance level of 0.05 or 95% confidence is used. For the sample distributions
25 to come from the same populations the significance of the t-test must be greater than 0.05. The
26 Student's t -test was conducted using SPSS version 11.5.0 (SPSS, 2002) software. For a more
27 detailed description of the Student's t-test, the reader is referred to Helsel and Hirsch (1995).

28
29 The Mann-Whitney test, also known as the Wilcoxon rank sum test, is a non-parametric rank sum
30 test used to test the null hypothesis that data in two independent samples are taken from the same
31 population against the alternative hypothesis that they are from different populations. Being
32 non-parametric, the Mann-Whitney test makes no assumptions as to the underlying population of
33 the dataset. The Mann-Whitney test works by ranking all the values from low to high, and
34 comparing the mean rank in the two samples. In this analysis a significance level of 0.05 or 95%
35 confidence is used in comparing the means of samples. For the sample distributions to come
36 from the same populations the significance of the Mann-Whitney test must be greater than 0.05.
37 The Mann-Whitney test was conducted using SPSS version 11.5.0 (SPSS, 2002) software. For a
38 more detailed description of the Mann-Whitney test, the reader is referred to Helsel and Hirsch
39 (1995).

40
41 The comparisons were performed on all organic compounds detected within the 2005Q2 through
42 2007Q3 dataset.

1 **3.3.2 Organic Detections in Background Well Samples**

2 The organic detections in background well samples were compiled and reviewed to observe any
3 temporal or qualitative trends that may elucidate the nature of the exceedances. The review was
4 conducted using the same database.

2

1 **4.0 Results**

2 **4.1 General Observations**

- 3 • In all aquifers the background concentrations calculated for filtered samples were
4 generally less than those for unfiltered samples.
5
- 6 • The background concentrations derived by the different methods are typically of the same
7 magnitude for a particular analyte. Differences observed between the quartile and 95UTL
8 results were primarily where the sample distribution contained a large proportion of non-
9 detects. The quartile method is based primarily on the interquartile range which by
10 definition is the range of the middle 50% of the data. Where the middle 50% of the data
11 contains only zeros, the background concentrations calculated by the quartile method will
12 always be zero.

13 **4.2 Recalculating Background Values by Statistical Approach**

14 The results of the background concentration determination by statistical approach are shown in
15 Tables 4-1 through 4-4. Each table lists the original background value and the current estimate
16 based on each statistical procedure. The column labeled “% difference” compares the updated
17 estimate to the original value.
18

19 **4.2.1 95UTL Results**

20 The UTL approach produced more values that were higher than the original values. Only nine
21 elements were estimated lower than the original values. All of the nine came from filtered
22 samples (five from bedrock, four from unconsolidated groupings).
23

24 **4.2.2 Quartile Results**

25 Compared to the original values, the overall results from the quartile set were fairly evenly
26 spread between increases and decreases. However, all of the unconsolidated unfiltered results
27 were higher than the original values. All of the bedrock filtered results were lower than original
28 values.

1 Table 4-1. Statistical Results for Unfiltered Samples from the Unconsolidated Aquifer

COPC	Background Concentration (ug/l)				
	Original	95UTL		Quartile

4.3 Observations by Aquifer Groups and Geology

4.3.1 Unconsolidated Unfiltered Results

The background concentrations of all of the elements with original values that were not “zero” were increased through both the UTL and Quartile approach.

4.3.2 Unconsolidated filtered Results

The results were fairly evenly split among higher and lower results. The 95UTL approach resulted in five higher values and four lower values. The quartile produced six lower and four higher values. Aluminum was noted to gain a non-zero value.

4.3.3 Bedrock Unfiltered Results

All of the 95UTL values were higher than the original values for the unfiltered bedrock dataset. The quartile values were each a mix of higher/lower, with no distinct pattern among the elements.

4.3.4 Bedrock Filtered Results

The bedrock filtered dataset values calculated using the 95UTL approach were evenly mixed between higher and lower values compared to the original values. The quartile values were also mixed compared to the original values.

4.3.5 Geological Formation

The major geologic formations represented within the background wells are sandstone, shale and soil. The 95UTL results are shown in Table 4-5 and compared to the original estimates. Each of the formations produced a non-zero value for aluminum, antimony, cadmium, and mercury. Selenium produced non-zero values in sandstone and soil, but not in shale. The sandstone formation produced five increased values and five decreased values. Shale produced three higher values and seven lower values. The soil results showed six higher values and four lower values.

Table 4-5 Background Concentrations For Geological Formations and Soil (filtered)

COC	Background Concentration (ug/l)						
	Original	Sandstone		Shale		Soil	
		Concentration	% Difference	Concentration	% Difference	Concentration	% Difference

1 **4.4 Inorganic Background Well Sample Exceedances**

2
3 The results of the t-test are shown in Table 4-6. The results of the t-test comparisons indicate
4 that the COPCs can be classified into three distinct groups: Group 1 consisting of 11 analytes
5 whose distribution within the background wells and non-background wells are indistinguishable;
6 Group 2 consisting of 12 analytes whose distribution within the background wells and non-
7 background wells are distinguishable and may indicate groundwater impacts; and, Group 3
8 consisting of 1 analyte (barium), whose distribution within the background wells and non-
9 background wells is distinguishable but the average concentration of this COPC in non-
10 background wells is less than that in background wells indicating that barium is not impacting
11 groundwater. The Group 2 analytes would be considered those that are impacting groundwater.
12

13 The Mann-Whitney test generally supported the t-test results, with the exception of aluminum,
14 beryllium, cyanide, and nickel that had opposite results (see Table 4-7). Note that even though
15 the Mann-Whitney test results indicate the distribution of cyanide in background and non-
16 background wells are distinguishable, the average concentration of cyanide is lower in non-
17 background wells. Therefore cyanide is not impacting groundwater.
18

19 Additional investigations were conducted by comparing the time series plots of the data from
20 background and non-background wells along with the detection limit (see Appendix B). The
21 time series plots generally confirm the t-test and Mann-Whitney test results.
22

23 As with all statistical analyses, interpretation of the results must be approached with caution. For
24 both the t-test and Mann-Whitney tests to be effective the percentage of non-detects within the
25 dataset must be less than 40%. For most of the analyzed analytes the percentage of non-detects
26 is significantly greater than 40% as is shown in Table 4-8. Therefore with the exception of
27 barium, calcium, iron, magnesium, manganese, potassium, sodium, and zinc all results should be
28 considered with caution.
29

30 **4.5 Organic Background Well Sample Exceedances**

31 A total of 24,172 data results were produced from the background well samples collected within
32 the time interval of 2005Q2 and 2007Q3 (data provided in Appendix A). Within that, there were
33 a total of 357 detections of organic compounds. All but 22 of these detections were tagged with
34 qualifiers as listed in Table 4-9. The 22 validated results were detected between 2005 and 2006,
35 with eight bis(2-ethylhexyl)phthalate detections and four carbon disulfide detections. No
36 detections were observed in the 2007 dataset. Table 4-9 lists the quantity and qualification
37 category of compounds detected in background wells.
38

39 Table 4-10 provides a summary of the organic detections within background well samples. The
40 table shows that many of the organic compounds were detected infrequently when considered
41 within the entire background dataset. In addition, the impact of the variability in detection limits
42 (over an order of magnitude in some cases) and data qualifiers should be considered when
43 interpreting these data.

1 **5.0 Recommendations**

2 ***5.1 Background Calculations***

3 Overall, the two statistical approaches provided a distribution of values that were both higher
4 and lower than the original background values. The database is much stronger now than when
5 the original background values were calculated; therefore the current values may be more
6 reliable. The quartile approach focuses on values that fall outside the middle 50% of the data,
7 resulting in the loss of useful information and providing artificially low calculated background
8 concentrations. Therefore the 95UTL approach is recommended because it ensures that the
9 background concentration calculated encompasses 95% of the data used for background
10 analysis.

11 ***5.2 Managing Exceedances***

12 Using discrete background values to measure compliance offers a binary approach: the sample is
13 either less than or greater than the deemed background value. This approach may be useful as a
14 screening measure. However, for inorganic compounds, it may be prudent to consider the newly
15 developed approaches to determine background without comparing individual results.

16
17 For organic compounds, the conventional approach is to assume that any detection is an
18 exceedance. A method that incorporates interpretation such as the frequency of detection or
19 trends in detection, the qualification of the result and any other mitigating considerations would
20 render a more practical and useful basis for decision-making.

21
22 For both inorganic and organic data, the most meaningful approach is the one that best meets the
23 objectives of the FWGWMP as it moves forward. The objectives may change as the program
24 moves from delineation to remediation and risk-based closure. Therefore periodic review of the
25 background database is recommended.
